This post categorized under Roadside Attractions Category:Q: How to write a column based on the value of another column? I have a df like this: Date Value 2019-07-23 12:00:00+0000 100 I want to create a new column and assign the value of the "Value" column based on the maximum date value of the "Date" column. For example, in the previous example, there is a duplicate row of the "Date" column and the value of "Value" column is 100. Because the value of the "Value" column is 100, then the value of the new column is also 100. This is what I have done so far: for i in range(len(df.index)): if df['Date'].iloc[i] == df['Date'].max(): df['New_Column'] = 'Val_100' A: You can using numpy.where with axis=1 for process all rows at once 82157476af
